Abstract

Video-conferencing is expected to become increasingly important for tele-learning environments. In contrast to asynchronous, text-based computer-mediated communication, video-conferencing facilitates cooperation tasks that require highly frequent and continuous coordination. Typical kinds of such cooperation tasks are found in peer teaching settings. Despite the growing application of video-conferencing, only little is known about possibilities of enhancing collaboration in video-conferencing settings. This study investigates the effects of different types of support for cooperation on the learning outcomes of peer dyads in a video-conferencing scenario. The main research question is how cooperation scripts and content schemes enhance the students' cognitive activities and foster the outcomes of cooperative learning. Two factors were varied experimentally: The content scheme (with/without) and the cooperation script (with/without). 86 university students of educational psychology participated in the study. Each student of a dyad received a text dealing with a psychological theory in the field of the nature-nurture-debate. The students' tasks were (1) to teach their partners the relevant contents of their text and (2) to reflect ideas that went beyond the scope of the text. Results indicate that in particular the cooperation script enhances learning outcomes of collaborative knowledge construction.

Keywords: Collaborative knowledge construction, video-conferencing, content schemes, cooperation scripts

Zusammenfassung

Videokonferenzen werden für die Gestaltung netzbasierter Lernumgebungen zunehmend interessant. Im Gegensatz zu asynchroner, textbasierter computervermittelter Kommunikation, ermöglichen Videokonferenzen Kooperationsaufgaben, die einen hohen Grad an Koordination erfordern. Typische Beispiele hierfür sind Peer-Tutoringbzw. Peer-Teaching Arrangements. Trotz der zunehmenden Bedeutung von Videokonferenztechnologien ist bisher nur relativ wenig hinsichtlich der Förderung kooperativen Lernens mit diesem Medium bekannt. Diese Studie untersucht die Effekte verschiedener Fördermaßnahmen auf Ergebnisse der gemeinsamen Wissenskonstruktion beim dyadischen Lernen in einer Videokonferenz. Untersucht wird hierbei der Einfluss eines Kooperationsskripts und eines inhaltlichen Strukturschemas. In einem zweifaktoriellen Design wurden die beiden Einflussfaktoren Kooperationsskript (mit/ohne) und inhaltliches Strukturschema (mit/ohne) experimentell variiert. 86 Studierende der Pädagogik nahmen an der Studie teil. Jeder Teilnehmer erhielt einen Text über eine psychologische Theorie zum Thema der Anlage-Umwelt Debatte. Die Aufgabe der Studierenden bestand darin, (1) dem Lernpartner die relevanten Inhalte des eigenen Theorietextes zu vermitteln und (2) Ideen, die über die Inhalte des Textes hinausgingen zu elaborieren. Die hier vorgestellten Ergebnisse zeigen, dass insbesondere das Kooperationsskript den Lernerfolg steigert. Weitere Prozessanalysen sind notwendig.

Schlüsselwörter: Gemeinsame Wissenskonstruktion, Lernen in Videokonferenzen, Wissensschemata, Kooperationsskripts

FOSTERING COLLABORATIVE KNOWLEDGE CONSTRUCTION IN DESKTOP VIDEO-CONFERENCING. EFFECTS OF CONTENT SCHEMES AND COOPERATION SCRIPTS IN PEER TEACHING SETTINGS

Introduction

Research on cooperative learning in video-conferencing has become increasingly interesting for educational psychology. The rapid developments in the field of information and communication technology suggest that video-conferencing will be intensively applied in educational institutions in the near future, since it enables synchronous forms of collaborative distance learning which allow very frequent and complex interactions. So far, research in this field has mainly aimed at investigating differences with respect to interaction and communication between video-conferencing and other modes of cooperation, in particular face-to-face and asynchronous text-based cooperation. Yet, only a few studies in the field of video-conferencing have focused on processes and outcomes in the context of learning. This study tries to bridge this gap by investigating effects of content schemes and cooperation scripts on processes and outcomes of collaborative learning in video-conference settings.

Theoretical framework

Contents, processes, and outcomes of collaborative knowledge construction in face-to-face and video-conference settings

Learning contents and learning processes

So far, only a few studies on video-conferencing have analyzed collaborative knowledge construction systematically. The analyses and descriptions of collaborative knowledge construction basically discriminate content-related and process-related aspects. Regarding the content level, a major question concerns the distinction between *on-task* and *off-task* contents. In particular, it has been analyzed to what extent, how frequently, or how adequately learners talk about relevant contents of the learning task (e.g. Cohen, 1994). Another aspect of content-related aspects that is especially relevant in the context of video-conferencing concerns the *coordination* of learning activities. When analyzing discourse processes in video-conference settings, Fischer, Bruhn, Gräsel, and

Mandl (in press, b) distinguish between *task-related* and *technology-related* coordination. According to them, task-related coordination during collaboration is positively correlated with individual learning outcomes. Moreover, they conclude that there are no significant differences between collaboration in video-conferencing and in face-to-face settings, neither concerning task-related coordination nor concerning technology-related coordination.

In addition to discourse contents, other approaches include the analysis of process-related aspects of collaborative knowledge construction. Webb (1991), for example, analyzed explanations with different levels of elaboration, whereas Graesser and Person (1994) focused on questions in tutoring discourse. Fischer, Bruhn, Gräsel, and Mandl (1998) presented an approach that analyzed four processes of collaborative knowledge construction: (1) Externalization refers to the process of contributing prior individual knowledge. This exchange of different individual concepts is considered to be the starting point of negotiating common meaning. (2) Elicitation refers to the strategy of using the learning partner as a resource (Dillenbourg, Baker, Blaye, & O'Malley, 1996). Learners cause each other to externalize task-related knowledge: By asking questions, for example, they induce their partners to give explanations. Thereby, elicitation can be responsible for activating deeper comprehension processes (e.g. King, 1994). (3) Conflict-oriented negotiation, another aspect of collaborative knowledge construction, refers to the concept of socio-cognitive conflict (cf. Dillenbourg, 1999; Doise & Mugny, 1984; Nastasi & Clements, 1992). Socio-cognitive conflict occurs in situations in which learning partners externalize different or contrasting interpretations related to the learning task. This conflict often results in modifications of knowledge representations. (4) Apart from conflict-oriented negotiation, another way of reaching a consensus is the *integration* of different individual perspectives into a common interpretation or solution of the given task. However, although this form of consensus-building can be helpful under some conditions, it involves the risk of turning into a conflict-avoiding cooperation style. Considering current empirical findings, Fischer, and Mandl (2000a) conclude that there are no substantial differences between video-conferencing and face-to-face settings concerning the processes of knowledge construction described above.

Learning outcomes

Research on cooperative learning focusses on different concepts of *learning outcomes*. Frequently, individual outcomes of cooperative learning are in the center of research interest. Thus, cooperative learning efforts aim at the development of individual cognitive, socio-cognitive or affective abilities (e.g. Slavin, 1996). In contrast to the focus on individual learning outcomes, other approaches emphasize the importance of collaborative outcomes, which are achieved

by a joint solution of the given cooperation task (e.g. Scardamalia & Bereiter, 1993). In a recent study, Bruhn (2000) found that (1) dyads in the video-conferencing environment attained similar collaborative outcomes compared to dyads in a face-to-face setting, and that (2) learners in the two different settings did not differ with respect to individual outcomes. Similar to the findings concerning the learning processes, these results show that the different measures of learning outcomes do not differ substantially from each other in video-conferencing and face-to-face settings.

Fostering collaborative knowledge construction in face-to-face settings

The interactions described above, which are seen to be critical for effective cooperative learning, do not occur automatically. Typical barriers to effective cooperative learning are for example the diffusion of responsibility, social loafing, the dysfunctional division of labor, or a lack of learning skills on the part of the students (Johnson & Johnson, 1992; Salomon & Globerson, 1989). Renkl and Mandl (1995) specify important factors that are responsible for the success of cooperative learning: It depends on the nature of the given task, individual characteristics of the learners (which either support or interfere with cooperative learning activities) or the reward structure of the learning situation. Yet, the most critical kinds of interventions aim at fostering learning processes by guiding learners' interactions during collaboration.

One well-known and effective way to evoke learning activities in cooperative settings is to distribute different learning materials among the learners that should first be worked through individually. The subsequent cooperation task is to teach the learned material to each other. We label this kind of arrangement *peer teaching*, assuming that the learning partners possess similar learning skills but vary concerning the knowledge they acquired in the individual learning phase. Thus, peer teaching is distinguishable from peer-tutoring arrangements in which partners differ from each other in status and learning experiences with respect to the content (O'Donnell & Dansereau, 2000).

Peer teaching arrangements evoke learning activities by defining two different roles: the explainer and the learner. While the role of the explainer generally involves processes like providing information and responding to questions, the learner-role is defined by activities like asking questions. In this way, peer teaching settings trigger processes of collaborative knowledge construction in a 'natural' manner. Thereby, both the explainer and the learner may benefit from collaborating. For the explainer, learning by teaching is a significant mechanism that provides an opportunity to reformulate and extend knowledge structures. The learner, on the other hand, benefits from the one-to-one interactions in peer teaching settings: He or she not only gets the chance to immediately ask

questions if necessary, but also to receive individual feedback by the explainer. Empirical findings (e.g. O'Donnell & Dansereau, 2000) indicate that peer teaching is an effective method of instruction. Yet, it has to be considered that peer teaching is a complex process of interaction which demands a great deal of the learners. Therefore, the question is how interaction and collaborative knowledge construction can be improved in peer teaching settings. At least two possibilities of fostering the interaction processes are conceivable: (1) supporting learners with content-specific structures which can facilitate the construction of new knowledge and (2) providing a cooperation script in order to evoke conducive processes of collaborative knowledge construction. Both treatments are considered to be helpful for cooperative learning in general. Therefore we will discuss both strategies in a broader context that goes beyond the scope of peer teaching settings below.

Pre-structuring task-specific contents. In order to improve collaboration by content-specific structuring methods, the learners receive some kind of visualization, such as a diagram or a table with central, yet abstract characteristics of the contents discussed during their collaboration. Fischer, Bruhn, Gräsel, and Mandl (in press, a) present empirical findings which indicate that content-specific structuring methods can foster processes and outcomes of collaborative knowledge construction. Dyads which worked with a pre-structured visualization tool not only externalized and elicited more task-related knowledge, but also benefited with respect to the quality of a collaborative problem solution when compared with dyads of a control group that received a non-structured visualization-tool. Suthers (in press) compares different kinds of representations (textual, graphical, and matrix) learners had to work on during collaboration in order to facilitate their learning processes and outcomes. According to him, the variation in the features of the representational tools can significantly affect the learners' knowledge building discourse. We assume that these kinds of content-specific structuring methods facilitate interaction processes in peer teaching by supporting both the peer in the explainer role and the peer who takes the role of the learner. They (1) can support the explainer in structuring the contents to be taught and (2) can provide 'anchors' for the learner to integrate the new knowledge.

Providing Cooperation Scripts. One of the most well known techniques which defines roles including specific cognitive activities is the scripted cooperation technique (O'Donnell, 1999). It was developed for learning dyads and can be applied to a variety of tasks. A prototypical cooperation script used with a text comprehension task includes the following steps: (1) Both partners read the first section of a text, (2) partner A recalls the text information without using the text, (3) partner B provides feedback without looking at the text, (4) both partners

elaborate on the text information, (5) both partners read the second section of the text, switch roles and continue with steps 1 to 4 (O'Donnell & Dansereau, 1992). Several studies have documented the effectiveness of this technique for cooperative learning (O'Donnell, 1999).

Another well-known instructional method for cooperative learning is *reciprocal teaching* (Palincsar & Brown, 1984). The reciprocal teaching technique designates roles that include the strategies questioning, summarizing, clarifying and predicting (Palincsar & Brown, 1984). Evidence for the effectiveness of these techniques comes from numerous studies (Rosenshine & Meister, 1994). Studies about the effects of cooperation scripts usually compare groups who have been trained in applying the collaboration strategy with control groups which received no training. Thus, in contrast to methods merely using resource interdependence to evoke cooperation processes, techniques like scripted cooperation or reciprocal teaching generally include a prior training for the students working on a cooperation task.

A major advantage of techniques that explicitly aim at scripting cooperation – as described above – is that they support learners in effectively interacting with each other. So far, the effectiveness of these techniques has been documented mainly within face-to-face settings. Our approach is to apply these techniques within a video-conference setting.

Fostering collaborative learning in video-conference settings

Due to the rapid progress in the field of communication technology, videoconferencing is more and more becoming an application for everyday use and can also be expected to be a helpful extension concerning the design of new learning environments. Yet, up to now only a few studies on video-conferencing have raised the question of how to foster collaborative learning in videoconferencing. The question is, to what extent the approaches developed in face-to-face settings can also be applied to the context of video-conferencing. In general, we believe that interventions that have been shown to be effective in face-to-face settings as described above can also be helpful for fostering cooperative learning in video-conferencing. Yet, we also see some differences. Whereas techniques like peer teaching and the provision of content structures or cooperation scripts can be transferred to video-conference settings, the training of role skills in distance learning is an obstacle since the learners are located in different places. Yet, net-based learning environments provide the possibility to implement treatments not only by preliminary training but also by structured interfaces. This implementation strategy is well known in text-based computer-mediated learning environments. For example, Baker and Lund (1997) structured the text-based communication among learners working together on a problem-solving task by providing a structured communication interface which included so-called "communicative act buttons". These buttons aimed at facilitating the interaction between the learners and at encouraging the learners to engage in effective collaboration activities. Buttons labeled for instance with "Where do we start?" or "What should we do now?" tended to facilitate coordination and evoke meta-cognitive processes. Empirical findings indicate that the structured interface is able to promote interactions that enable learners to collaborate effectively on a problem-solving task.

Aims of the study

The aim of the presented study is to investigate two different possibilities to facilitate collaborative knowledge construction in video-conferencing. Therefore, we arranged a peer teaching setting in which two similarly experienced university students collaborated on a text comprehension task. Both learners were asked to teach each other the contents of a theoretical text they had read individually in a preceding text acquisition phase. The two variables varied in the experiment were (1) a text-based content scheme including guiding questions to facilitate collaborative text comprehension and (2) a cooperation script aiming at directing processes of collaborative knowledge construction. Both treatments were not implemented as a preliminary training of the participants. Instead we pre-structured the shared visual interface the learners worked on during collaboration. Our research questions are:

- 1. How does the content scheme influence the learning outcomes in a videoconferencing peer teaching setting?
- 2. How does the cooperation script influence the learning outcomes in a videoconferencing peer teaching setting?
- 3. How does the interaction of the content scheme and the cooperation script influence the learning outcomes in a video-conferencing peer teaching setting?

Method

Setting

The scenario consisted of a desktop video-conferencing system including audio- and video-connection and a shared screen to support the dyads' knowledge construction. In this way, the setting allowed synchronous verbal communication and joint creation of text material. The shared application was realized with MS-Netmeeting 3.01. As text-editor we applied MS-Word 2000, an application that we expected to be well known among our participants and therefore easy to handle. This technical solution enabled the learners to alternately type or edit notes in the text-editor. Since we de-activated most of the Word-facilities, the participants were merely able to create text-material. The creation of tables or diagrams was not possible. The reason for this restriction was to focus the participants' activities on learning-relevant processes by reducing the amount of non-content talk.

Participants

96 students in their first semester who were enrolled in educational introductory courses at the Ludwig-Maximilians-University of Munich took part in this experiment. Participation was required for receiving a course credit at the end of the semester, even though learning outcomes of the experimental session were not accounted for the final students' performance appraisals. Dyads were set up and randomly assigned to one of four conditions (three experimental conditions and a control group). Learning partners in general did not know each other before the experimental session. The partners were seated in two different rooms where they stayed during the experiment. For data analysis we excluded 5 dyads, since in these groups at least one member had substantial problems with the German language.

Design

The design of the study is shown in Table 1. A 2x2x2 factorial design was used. The two factors were (1) content scheme, (2) cooperation script and (3) cooperation role. Three experimental groups and a control group were formed. The experiment was conducted in one session that consisted of two main phases. During the individual text acquisition phase two different theory texts were distributed, one for each partner. In the following collaborative learning phase, the dyads were asked to work together using a desktop video-conferencing system to teach the contents of each text to the fellow learner. Thus, each learner took two roles: the *explainer-role* when explaining his or her theory to the

fellow learner and the *learner-role* when receiving information from the partner. Two text documents (one per theory) were provided on the shared screen to allow the documentation of important discussion contents. In the *unscripted/scheme group*, the text documents were structured in such a way that they included several guiding questions stressing the content of that text which were supposed to direct the dyads' discussion throughout this phase. In the *scripted/non-scheme group*, the two text documents included instructions about the explainer- and learner-role in order to effectively direct the learners' interaction. Dyads in the *structured/scheme group* worked with text documents that included the guiding questions as well as the cooperation script. Participants in the *unscripted/non-scheme group*, which served as control group, worked with two text documents that only included the name of the particular theory as a headline without any further aids.

Table 1: Experimental design of the study.

| | | Cooperation script | |
|----------------|---------|--|--|
| | | without | with |
| Content scheme | without | unscripted/non-scheme group (n = 12 dyads) | scripted/non-scheme group (n = 11 dyads) |
| | with | unscripted/scheme group (n = 10 dyads) | scripted/scheme group (n = 10 dyads) |

Content scheme. The content scheme was implemented by a pre-structured shared text document that contained eight guiding questions. Table 2 shows the questions of the content scheme.

Table 2: Questions included in the content scheme.

theory?

Empirical Findings Theory What are the most important con-How was the theory examined? cepts of the theory? What were the results of the empi-What are the main ideas of the rical studies? theory? Individual Estimation Consequences pedagogical interventions • What do I like/dislike about the Which can be concluded from the theory? theory? Which of my own experiences Which limits of pedagogical interventions can be concluded from the support/do not support the theory?

The structure of the scheme was adopted from Brooks and Dansereau (1983) and adapted in accordance with the purposes of our study. As can be seen in Table 2, the content scheme was divided into four sections comprising two questions each. The different sections stressed important aspects including concepts and main ideas of the theory, empirical findings, consequences and individual estimations regarding the theory. Participants were asked to generate answers to all questions and write them down in the text document. Both theory texts did not provide any information concerning the questions regarding the consequences and the individual estimation. By answering these questions, the participants were expected to draw conclusions that go beyond the scope of the texts.

Cooperation script. Learners in these conditions also received a pre-structured text document. This text document included a short description of the explainer-and learner-role and directed the learners' interactions during the collaborative learning phase by defining four steps of interaction: (1) explaining the text material (explainer) and asking comprehension questions (learner), (2) typing the information received (learner) and supporting the learner (explainer), (3) generating own ideas concerning the theory (explainer and learner individually), and (4) discussing (explainer and learner) and writing down the results of the discussion (learner only, see Table 3). An observer, who stayed in one of the two rooms, supervised the correct application of the specified roles and controlled the time in which the different tasks were to be completed. After the discussion of the first theory had finished, the partners changed roles and repeated the same procedure, now discussing the second theory. Time-on-task for each theory was 40 minutes.

Table 3: Steps and learning activities included in the cooperation script.

| | Explainer | Learner | |
|-----------------------------|--|---|--|
| Step 1 (approx. 10 min.) | Explaining the text material | Asking comprehension questions | |
| Step 2 (approx. 15 min.) | Supporting the learner's activities | Explaining and typing the in- formation received in the shared text document | |
| Step 3 (approx. 5 min.) | Elaborating on text information individually | | |
| Step 4 (approx. 10 min.) | Discussing generated ideas with the partner | Discussing generated ideas with the partner and writing the results in the shared text document | |

Dyads in the unscripted groups received no instructions with respect to the structuring of their interactions. In accordance with the time given in the scripted groups, time-on-task for both theories was 80 minutes. The partners in the unscripted groups were able to decide how much time they wanted to spend discussing each theory within the given time frame. For example, if they decided to take 50 minutes discussing the first theory, they only had 30 minutes left for the second theory.

Text materials

As mentioned above, two different theory texts were distributed between the two partners of each dyad. Both texts contained theories associated with the nature-nurture-debate. One partner read a text about "Attribution Theory" as developed by Bernhard Weiner, the other one about the "Theory of Genotype-Environment Effects" by Sandra Scarr. Both texts comprised approximately 1400 words each. The texts provided information on the foundations of the particular theory, its main concepts and on important empirical findings.

Procedure

Introduction and Pretests. The procedure of the experiment is shown in Table 4. At the beginning of the experiment, the dyad partners were seated in two different rooms and were informed about the aims of the session. They were told that at first they would learn about one theory with implications for the nature-nurture-debate individually, while their partner would learn a different theory, also concerning this topic. The task of the whole session would be to learn two important psychological-pedagogical theories. After that, the participants received the pretests as described below.

Individual text acquisition phase. In this phase, participants received a text either about the attribution theory or about the theory of genotype-environment effects. Each learner was informed about his/her task to explain the contents of the studied text to his/her partner after the individual acquisition phase. Both learners were given 25 minutes to read the text, underline important parts and take notes of the most important aspects if they wanted to. After that, the participants were given 10 minutes to think about how to explain the contents to their partners.

Collaborative learning phase. Prior to the actual learning interaction, participants were instructed on how to use both the video-conferencing system and the shared text documents. It was demonstrated how each partner could work on the same text document. Further, the participants were familiarized with the different tasks they had to accomplish according to the different conditions. The

dyads were told that they should use the text documents as a worksheet providing a basis for discussion. The cooperation task required both participants to comprehend both theories as deeply as possible. In all sessions, an observer stayed in one of the two rooms to supervise the correct performance of the particular tasks. In the scripted conditions, he/she also provided the participants with information about the time and switched from one phase to another. The collaborative learning phase took 80 minutes.

After the collaborative learning phase, the participants were asked to complete three tests assessing their level of knowledge acquisition (see below).

Data sources

Pretests. At the beginning of the experimental session, the participants were asked to fill out two knowledge pre-tests (one short answer- and one multiple choice-test) concerning concept-knowledge and deeper understanding of the theories to be learned. For analyzing the previous knowledge, we computed a combined cued recall measure consisting of the short answer- and the multiple-choice-test. In both cued recall tests (Attribution Theory and Theory of Genotype-Environment Effects) the highest possible score was 12 points.

Posttests. The post-tests included knowledge tests regarding concept-knowledge and deeper understanding which were similar to the pre-tests described above. Both cued recall tests (short answer and multiple choice) are assumed to measure a deeper and more detailed understanding of the theoretical concepts and their relations. Again, we computed a combined cued recall measure consisting of the short answer and the multiple-choice test. In both cued recall tests, the highest possible score was 16 points. In addition, the students were asked to take a free recall-test concerning their recall of concepts of the theories learned during the experimental session. The maximum scores in the free recall tests were 22 points (Attribution Theory) and 27 points (Theory of Genotype-Environment Effects).

Results

In order to control the effects of the pre-knowledge we computed a 2x2x2 Analysis of Variance (ANOVA) with the cued recall pre-tests as dependent measure. The between-groups factors were cooperation role (explainer or learner), content scheme (with or without) and cooperation script (with or without). Results showed no statistically significant differences between the groups neither regarding "Attribution Theory" nor "Theory of Genotype-Environment Effects" (F(1,78) = .96., n. s.).

In order to check if the two test types (free recall vs. cued recall) used in this study represent relatively independent knowledge measures, we computed correlations between the different outcomes. In fact, it turned out that the free recall and cued recall measures in both theories did not correlate significantly: The correlation between free recall and cued recall of "Attribution Theory" was r = .06 (n. s.), the correlation between free recall and cued recall of "Theory of Genotype-Environment Effects" was r = .04 (n. s.). Yet, we found that both free recall measures correlated significantly. The correlation between free recall of "Attribution Theory" and free recall of "Theory of Genotype-Environment Effects" was r = .22 (p < .05). There was no significant correlation between the two cued recall measures (r = -.06, n. s.). These results confirm our assumption that the free recall and cued recall measures capture two different types of knowledge. Therefore, we will treat each knowledge measure separately in our further analyses.

Below, results concerning learning outcomes in the different knowledge tests are presented. For a better illustration, the results are described separately for each theory.

Attribution Theory

In order to analyze effects of the factors cooperation role, content scheme and cooperation script on learning outcomes, we computed a 2x2x2 ANOVA with free and cued recall tests of "Attribution Theory" as dependent measure. Means and standard deviations of both measures are presented in Table 4. A significant effect of the cooperation role was found for the analysis of the cued recall score (F(1,78) = 19.78; p < .01). The participants who taught the Attribution Theory significantly outperformed those who took the role of the learner (M = 11.03, SD = 1.91 and M = 8.92, SD = 2.37, respectively). Neither concerning the free recall nor the cued recall test, did other effects reach statistical significance. That means that both treatments – content scheme and cooperation script – did not lead to significant effects on learning outcomes concerning "Attribution Theory".

Table 4: Results concerning free and cued recall of "Attribution Theory".

| | | Free recall of "Attribution Theory" | Cued recall of "Attribution Theory" |
|-----------|------------------------------------|-------------------------------------|-------------------------------------|
| | | M (SD) | M (SD) |
| | unscripted/ non-scheme group | 6.58 (5.16) | 11.43 (1.56) |
| Explainer | unscripted/ scheme group | 8.00 (4.16) | 10.67 (2.65) |
| | scripted/ non-scheme group | 7.36 (3.17) | 10.78 (3.36) |
| | scripted/ scheme group | 5.40 (4.67) | 11.21 (3.94) |
| | unscripted/ non-scheme group | 7.55 (3.50) | 9.28 (2.31) |
| Learner | unscripted/ scheme group | 7.90 (3.67) | 8.14 (3.02) |
| | scripted/ non-scheme group | 7.45 (4.95) | 8.94 (1.71) |
| | scripted/ scheme group | 6.00 (4.69) | 9.26 (2.54) |

Theory of Genotype-Environment Effects

With respect to the "Theory of Genotype-Environment Effects" we also computed an ANOVA with the factors *cooperation role*, *content scheme* and *cooperation script*. Means and standard deviations of both measures are presented in Table 5. Again, a significant effect of the *cooperation role* was found for the analysis of the cued recall score (F(1,78) = 8,15; p < .01). The peers who took the explainer role significantly outperformed those who took the learner role (M = 9.50, M = 2.54 and M = 7.93, M = 2.56, respectively). A slight effect of the *cooperation role* was also found in the free recall measure (F(1,78) = 2,83; P < .10). Again, the explainers outperformed their partners in the learner role (M = 10.90, M = 3.81 and M = 9.35, M = 4.29, respectively).

Table 5: Results concerning free and cued recall of "Theory of Genotype-Environment Effects".

| | | Free recall | Cued recall |

| | scripted/ non- scheme group | 11.91 (4.16) | 9.30 (2.91) |
| | scripted/ scheme group | 10.10 (5.30) | 10.29 (2.52) |
| | unscripted/ non- scheme group | 8.91 (4.78) | 7.15 (3.50) |
| Learner | unscripted/ scheme group | 9.50 (4.03) | 7.28 (1.79) |
| | scripted/ non- scheme group | 10.27 (3.50) | 9.07 (5.98) |
| | scripted/ scheme group | 8.70 (5.17) | 8.27 (1.70) |

Additionally a significant main effect was found concerning the free recall measure with respect to the factor *cooperation script*. This effect almost reached the 5 per cent significance level (F(1,78) = 3.27; p < .10). Peers who cooperated in the scripted conditions outperformed the participants working without the cooperation script (M = 9.23; SD = 2.46 and M = 8.22; SD = 2.77, respectively).

No other effects concerning the free and cued recall tests reached statistical significance. Hence, the content scheme did not show to have significant effects on learning outcomes concerning the "Theory of Genotype-Environment Effects".

Discussion

Results show that peer teaching is an effective means for structuring cooperation between two learners. Obviously, compared to traditional classroom instruction, peer teaching helps students to actively engage in beneficial learning processes (Graesser & Person, 1994). Yet, it must be considered that peer teaching particularly supports those learners who take the role of the teacher. The results presented above clearly indicate these advantages on the explainer's part: In both theories the peers in the teacher role outperformed their partners who were taught the learning material. These results correspond to findings of studies that also focussed on peer teaching (e.g. O'Donnell & Dansereau, 2000). At least two reasons can be assumed as an explanation for the teachers' advantages. First, the better outcome performance can be ascribed to the higher amount of time-on-task that the explainers spent due to the individual acquisition of the material to be taught. The second explanation refers to the relevance of the so called *generation effect*. Due to the generation effect, overt verbal activity leads to better recall of information than listening to it (Foos, Mora, & Tkacz, 1994; Slamecka & Graf, 1978). Therefore, learners who get the chance to explain knowledge to others benefit from cooperative learning in particular. The design of this study does not permit to decide which of both interpretations is more relevant. Yet, when findings of other studies are taken into account, both factors (more time-on-task and higher level of activation) should be responsible for the advantages on the teacher's part (cf. Lambiotte et al., 1987, 1988).

The results of this study showed no significant effects of the content scheme on learning outcomes. Therefore one might deny the relevance of this treatment. Yet, this conclusion is precipitate when considering (1) the learning activities evoked by the content scheme and (2) the knowledge tested in the outcome measures. The content scheme supported students particularly in elaborating on the learning material. Elaborations are assumed to mainly facilitate long term retention since they help connecting the learned material to the knowledge base. That means that the effects of the content scheme might have failed to show because the outcomes were tested immediately after the learning session. Perhaps advantages of the content scheme would have appeared if

learning outcomes had been tested again at a later time. Unfortunately, this was not possible for organizational reasons.

In contrast to the content scheme, the cooperation script showed significant effects on learning outcomes. However, advantages of the scripted groups only occurred concerning the cued recall measure of the "Theory of Genotype-Environment Effects". One reason for the advantages of the cooperation script only in one theory might be that the effectiveness of the cooperation script is tied to the level of difficulty of the studied theory. A comparison of the outcomes of the two cued recall tests shows that concerning the "Attribution Theory", 84% of the participants reached more than half of the total score. In contrast, only 62% reached an equivalent score concerning the "Theory of Genotype-Environment Effects". This lower percentage indicates a higher degree of difficulty of the second theory. Therefore, the conclusion can be drawn that the cooperation script shows effects particularly with more complex learning material.

The two outcome measures (free recall and cued recall) used in this study seem to represent independent knowledge types. We assume that the free recall tests are associated with recall of concepts of the learned theories, whereas the cued recall tests require a deeper and more detailed understanding of the theoretical concepts and their relations. The findings show that the cooperation script affects the second kind of knowledge in particular. This means that learners working with the cooperation script mainly benefit with respect to a deeper comprehension of the learned concepts.

At present we can only present results concerning learning outcomes. In order to gain deeper insight into mechanisms of the varied treatments, additional analyses of learning processes are needed. Therefore we are currently working on a category system for discourse analysis. According to the assumptions described in the theoretical framework, the categories include content-related and process-related aspects. The content-related aspects refer to activities concerning the coordination of the collaboration activities, the discussion of text material and the elaboration on information of the text. Process-related aspects comprise activities concerning elicitation, externalization, and conflict- or consensus-oriented negotiation of on-task contents as well as the distribution of task-related activities among learners (such as writing down information in the shared document). We assume that such a detailed analysis of discourse will enable us to reveal critical factors correlated with recall performance.
