The novel tetrahalophosphonium salts $PBr_4^+AsF_6^-$, $PI_4^+AlCI_4^-$ and $PI_4^+EBr_4^-$ (E = Al, Ga) have been synthesised. A variety of solid complexes containing PBr_4^+ (e.g. $PBr_4^+AsF_6^-$, $PBr_4^+AlBr_4^-$, $PBr_4^+GaBr_4^-$), PI_4^+ (e.g. $PI_4^+AlCI_4^-$, $PI_4^+AlBr_4^-$, $PI_4^+GaBr_4^-$) or the mixed species $PBr_nI_{4-n}^+$ ($0 \le n \le 4$, containing $AlBr_4^-$, $GaBr_4^-$, AsF_6^- or SbF_6^-) have been studied by solid-state ³¹P MAS NMR and vibrational spectroscopy. The influence of the counter-ion on the chemical shift and the vibrational frequencies are discussed. The crystal structures of $PI_4^+AlCI_4^-$, $PI_4^+AlBr_4^-$ and $PI_4^+GaI_4^-$ are reported. Evidence for the existence of the hitherto unknown mixed bromoiodophosphonium cations PBr_3I^+ , $PBr_2I_2^+$ and $PBr_1I_4^-n^+$.

Introduction

The binary tetrahalophosphonium cations $PF_4^{+,1} PCl_4^{+,2,3}$ $PBr_4^{+2a,3,4}$ and PI_4^{+5-7} have been known for some time and were characterised by vibrational and ³¹P NMR spectroscopic studies. Additionally, several crystal structure determinations have been reported for PCl_4^{+} compounds with a large variation of the counter-ion.^{2a,8} PBr_4^{+} and PI_4^{+} have been characterised only by X-ray crystallography in the salts $PBr_4^{+}Br^{-,9}$ $PBr_4^{+}Br_3^{-10}$ and $PI_4^{+}AII_4^{-.11}$

Recently,⁶ we showed in a combined theoretical and experimental study, that the PI_4^+ cation has an extremely large negative ³¹P chemical shift in the compounds $PI_4^+AsF_6^-$ ($\delta = -519$) and $PI_4^+SbF_6^-$ ($\delta = -517$), which is due to spin-orbit (SO) contributions from the four heavy iodine substituents, transmitted to the phosphorus nucleus by a very effective Fermi-contact mechanism. The less negative solid-state ³¹P NMR chemical shifts found in the polymeric $PI_4^+AII_4^-$ ($\delta = -305$) and $PI_4^+GaI_4^-$ ($\delta = -295$), suggest that the P-I bond orders are reduced due to intermolecular I · · · I interaction between PI_4^+ cations and EI_4^- (E = AI, Ga) anions.⁶ PCI_3Br^+ , $PCI_2Br_2^+$ and $PCIBr_3^+$ have been characterised by

PCl₃Br⁺, PCl₂Br₂⁺ and PClBr₃⁺ have been characterised by ³¹P NMR and Raman spectroscopy in solids and solutions containing mixtures of the chlorobromophosphonium cations PCl_nBr_{4-n}⁺ ($0 \le n \le 4$).^{3,12} Replacement of a chlorine by a bromine causes an upfield shift of about 40 ppm. Solution-state ³¹P NMR studies showed that there is a characteristic chemical shift range dependent upon the nature of the counter-ion present. The variation of the ³¹P chemical shift for PCl_nBr_{4-n}⁺ ($0 \le n \le 4$) as a function of the anion in the solid-state is even larger.³ The mixed chloroiodophosphonium cations PCl₃I⁺ and PCl₂I₂⁺ formed from the reaction of PI₃ with the strongly acidic solvent HSClO₃ were characterised by means of solution-state ³¹P NMR spectroscopy.¹³

To our knowledge, prior to this study there had been no

evidence for the existence of the mixed tetrahalophosphonium cations $PBr_nI_{4-n}^+$ ($1 \le n \le 3$). Only the existence of the PBr_3I^+ cation has been assumed in the reaction of PBr_3 and I_2 in acetic anhydride in a conductivity study.¹⁴

In this paper we report the preparation and characterisation of a complete series of the mixed bromoiodophosphonium cations by means of solid-state ³¹P MAS NMR spectroscopy. To allow unequivocal assignment, we have computed the ³¹P NMR chemical shifts of the free cations PBr_nI_{4 - n}⁺ ($0 \le n \le 4$) by density functional theory (DFT) methods corrected for SO coupling. The results of the ³¹P MAS NMR and the vibrational spectra clearly indicate that the counter-ion has a dramatic influence on the chemical shift and the vibrational frequencies of the tetrahalophosphonium species. Additionally, PI₄⁺-AlCl₄⁻, PI₄⁺AlBr₄⁻ and PI₄⁺GaI₄⁻ have been structurally characterised by single-crystal X-ray diffraction.

Results and discussion

Synthesis

Tetrabromophosphonium hexafluoroarsenate, $PBr_4^+AsF_6^-$, was prepared by the reaction of one equivalent of PBr₃ with one equivalent of $Br_3^+AsF_6^-$, reaction 1, eqn. 1, in CFCl₃.

$$PBr_3 + Br_3^+ AsF_6^- \xrightarrow{CFCl_3} PBr_4^+ AsF_6^- + Br_2$$
(1)

The colourless product formed was characterised by solidstate ³¹P MAS NMR and vibrational spectroscopy. Additionally, we recorded the solid-state ³¹P MAS NMR spectra of PBr₄⁺AlBr₄⁻ and PBr₄⁺GaBr₄⁻, which were prepared according to the literature.^{2e} PI₄⁺AlBr₄⁻ and PI₄⁺GaBr₄⁻ were prepared from the reaction of PI₃ with IBr and EBr₃ (reactions 2 and 3, E = Al, Ga) in a 1:1:1 molar ratio, eqn. 2, in CS₂ under nitrogen.

$$PI_{3} + IBr + EBr_{3} \xrightarrow{CS_{2}} PI_{4}^{+}EBr_{4}^{-}$$

Solid-state ³¹P and ⁷¹Ga MAS NMR studies (see below) showed that for $PI_4^+GaBr_4^-$ the tetrabromogallate(III) anion is partly substituted by mixed bromoiodogallate anions, arising from a halogen exchange during the preparation.

Tetraiodophosphonium tetrachloroaluminate, $PI_4^+AlCl_4^$ was obtained from the reaction of PI_3 with ICl and $AlCl_3$ in a 1:1:1 molar ratio, reaction 4, eqn. 3, in CS_2 .

$$PI_{3} + ICl + AlCl_{3} \xrightarrow{CS_{2}} PI_{4}^{+}AlCl_{4}^{-}$$
(3)

The synthesis of pure compounds containing the mixed bromoiodophosphonium ions is extremely difficult. Attempts to prepare pure PBr₃I⁺ species were unsuccessful. Initial preparations involving reactions of PBr₃ with $I_3^+MF_6^-$ (reactions 5 and 6, M = As, Sb) in CFCl₃ or PBr₃ with IBr and EBr₃ (reactions 7 and 8, E = Al, Ga) in CS₂, led to products which were obviously mixtures of PBr_nI_{4-n}⁺.

All products reported here exist only in the solid-state. Dissolving *e.g.* $PI_4^+AlBr_4^-$ in CS₂ gives a solution that contains essentially the starting materials, while $PBr_4^+AsF_6^-$ is not soluble in common solvents.

Structures

The P–X distances and X–P–X angles for the isolated tetrahalophosphonium cations $PBr_nI_{4-n}^+$ ($0 \le n \le 4$), computed at the MP2 level of theory, are summarised in Table 1. The results for PBr_4^+ and PI_4^+ agree very well with the available X-ray data.

The unit cell of $PI_4^+AlBr_4^-$ is shown in Fig. 1, selected bond lengths and angles are listed in Table 2. $PI_4^+AlBr_4^-$ crystallises in the monoclinic space group $P2_1/c$ with four molecules in the unit cell. The PI_4^+ unit has a considerably distorted tetrahedral geometry. The P–I bonds are almost equal: 2.376(3)– 2.387(4) Å, the I–P–I bond angles range between 107.4(1) and 112.0(1)°. The $AlBr_4^-$ anion is also significantly distorted exhibiting bond angles between 107.3(2) and 116.8(5)° and Al-Br distances between 2.290(5) and 2.314(4) Å, which are comparable with the bond lengths found in $SeBr_3^+AlBr_4^{-.15}$

 $PI_4^+GaI_4^-$ (Fig. 2, Table 3) crystallises in the orthorhombic space group $Pna2_1$ with four molecules in the unit cell. The structure is isotypic with $PI_4^+AII_4^{-.11}$ The tetrahedra of the cations and anions are significantly distorted, exhibiting I–E–I angles between 106.9(1) and 112.6(1)° (PI_4^+) and between 107.12(6) and 112.90(5)° (GaI_4^-). P–I distances vary from 2.378(4) to 2.423(4) Å, Ga–I distances from 2.510(1) to 2.573(2) Å. P–I bond lengths and I–P–I bond angles are comparable to those found in $PI_4^+AII_4^{-.11}$

The average P–I bond length of $PI_4^+AlBr_4^-$ (2.381(4) Å) is significantly shorter than the average P–I bond length found in $PI_4^+GaI_4^-$ (2.408(4) Å). Similar to $PI_4^+AlI_4^-$ the molecular

structure of $PI_4^+GaI_4^-$ shows rather short interatomic $I \cdots I$ distances in the range of 3.357(2)-3.430(2) Å (Fig. 2) between the PI_4^+ and the GaI_4^- units, which are significantly shorter than the sum of the van der Waals radii (*ca.* 4.30 Å),¹⁶ indicating strong cation \cdots anion interactions, while the crystal structure of $PI_4^+AIBr_4^-$ shows considerably weaker interatomic $I \cdots Br$ contacts of 3.380(2)-3.449(2) Å (sum of van der Waals radii: *ca.* 4.10 Å,¹⁶ Fig. 1).

The crystal structure of $PI_4^+AlCI_4^-$ (Fig. 3, Table 4), which is isotypic with $PI_4^+AlBr_4^-$, displays a more isolated character for PI_4^+ in this species, exhibiting rather short P–I bond distances (2.361(4)–2.371(4) Å), significantly diminished interatomic I · · · Cl distances (3.315(8)–3.511(3) Å, sum of van der Waals radii: *ca.* 3.95 Å)¹⁶ and a less distorted tetrahedral geometry (108.8(2)–110.5(2)°) compared to the structures of $PI_4^+GaI_4^$ and $PI_4^+AlBr_4^-$.

Solid-state ³¹P NMR spectroscopy

 PX_4^+ salts. The solid obtained by the reaction of PBr₃ and Br₃⁺AsF₆⁻ (reaction 1, Table 5) gives a ³¹P MAS NMR

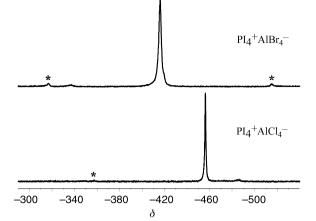

Fig. 4 MAS solid-state ³¹P NMR spectra of $PI_4^+AlBr_4^-$ and $PI_4^+AlCl_4^-$ at a spinning frequency of 20 kHz. Asterisks denote spinning side bands.

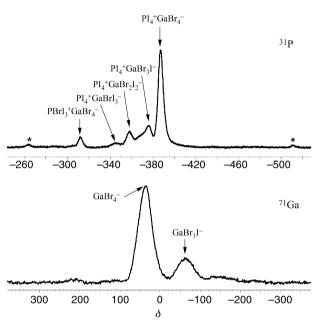

Fig. 5 MAS solid-state ³¹P and ⁷¹Ga NMR spectra for reaction 3 ($PI_3 + IBr + GaBr_3$) at a spinning frequency of 25 and 27 kHz, respectively. The isotropic chemical shifts are indicated by arrows. Asterisks denote spinning side bands.

spectrum consisting of a single resonance of chemical shift -83 ppm. The ³¹P chemical shift agrees with literature values reported for PBr₄⁺ compounds ($\delta = -72$ to -80)³ and can be assigned as PBr₄⁺AsF₆⁻. As expected,⁶ the comparison with the ³¹P MAS NMR chemical shifts of PBr₄⁺AlBr₄⁻ ($\delta = -79$) and PBr₄⁺GaBr₄⁻ ($\delta = -80$) shows that the chemical shift of PBr₄⁺AsF₆⁻ is slightly shifted to low frequency, due to the non-coordinating character of the counter-ion.

The ³¹P MAS NMR spectrum of $PI_4^+AlBr_4^-$ (reaction 2, Table 5, Fig. 4) shows one single resonance at $\delta = -416$, and is in the range between the isotropic shifts of the polymeric $PI_4^+GaI_4^-$ ($\delta = -295$) and the isolated $PI_4^+AsF_6^-$ ($\delta = -519$).⁶ This appears consistent with the molecular structure of $PI_4^+AlBr_4^-$, which might also be described as intermediate between these two extremes.

The ³¹P MAS NMR spectrum of the product of reaction 3 (PI₃/IBr/GaBr₃, Table 5, Fig. 5) shows one main signal at $\delta = -387$ (rel. int. 65%), which can be attributed to the isotropic shift of PI₄⁺GaBr₄⁻, as well as four other less intense resonances at $\delta = -376$ (rel. int. 18%), -358 (rel. int. 10%), -344 (rel. int. 2%) and -312 (rel. int. 5%).

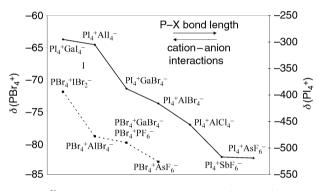

Fig. 6 31 P NMR chemical shifts for some PBr₄⁺ and PI₄⁺ species.

Fig. 6 summarises the ³¹P NMR chemical shifts of some PBr_4^+ and PI_4^+ species in the presence of different counteranions. The chemical shift of PX_4^+ is dependent on the nature of the counter-anion. Significant bridging cation ··· anion interactions in the lattice result in a weakening of the P-X bonds in PX_4^+ . The comparison of the crystal structures of $PI_4^+AlCl_4^-$, $PI_4^+AlBr_4^-$ and $PI_4^+GaI_4^-$ show a more isolated character for the PI_4^+ cations in $PI_4^+AlCl_4^-$ and $PI_4^+AlBr_4^$ with weaker interatomic cation · · · anion interactions and considerably shorter P–I bond lengths than found in $PI_4^+GaI_4^-$. The more isolated the cation, the more efficient is the Fermicontact mechanism that transfers the SO-induced spin density to the ³¹P nucleus.¹⁷ The ³¹P resonance is shifted to low frequency.⁶ In case of the PBr₄⁺ cation the chemical shift range is very small and varies from $\delta = -72$ to -83. In contrast, for PI₄⁺ species the anion has a significant influence. Due to much larger spin-orbit effects,⁶ the ³¹P chemical shift for PI₄⁺ salts varies over a considerably larger range, between $\delta = -295 (PI_4^+GaI_4^-)$ and $-519 (PI_4^+AsF_6^-)$. Thus, it is possible to take the low frequency ³¹P chemical shift as a measure of the intermolecular interactions. For mixed $PI_4^+ EBr_nI_{4-n}^-$ ($0 \le n \le 4$) species it is expected that a gradual replacement of bromine by iodine in the counter-anion causes a trend towards high frequency for the ³¹P chemical shift of PI_4^+ .

The ³¹P MAS NMR spectrum of the product of reaction 3 clearly indicates that halogen exchange resulting in a partial

substitution of the $GaBr_4^-$ by mixed tetrahalogenogallate(III) anions has occurred during the reaction. The resonances at $\delta = -376, -358$ and -344 with a decreasing relative intensity can be attributed to the chemical shifts of PI4+GaBr3I- $PI_4^+GaBr_2I_2^-$ and $PI_4^+GaBrI_3^-$. Moreover, the presence of different tetrahalogenogallate(III) anions in the solid obtained by reaction 3 was confirmed by solid-state ⁷¹Ga MAS NMR spectroscopy. The ⁷¹Ga MAS NMR spectrum (Fig. 5, Table 5) at a spinning frequency of 27 kHz reveals two broad resonances centred at $\delta = 37$ (rel. int. 78%) and -64 (rel. int. 22%). The ⁷¹Ga isotropic chemical shifts for the two resonances are comparable with the previous results of the solution-state ⁷¹Ga NMR studies for $GaBr_nI_{4-n}$ and can be assigned to the resonances of GaBr₄⁻ (δ^{71} Ga = 37 in the solid-state; δ^{71} Ga = 65 in solution)¹⁸ and $GaBr_3I^-$ ($\delta^{71}Ga = -64$ in the solid-state; $\delta^{71}Ga = -48$ in solution).¹⁸ The expected less intense signals for $GaBr_2I_2^-$ ($\delta^{-71}Ga = -173$ in solution)¹⁸ and $GaBrI_3^ (\delta^{71}Ga = -309 \text{ in solution})^{18}$ at higher field could not be resolved due to the large linewidths of the 71Ga resonances and overlapping spinning side bands. Similar halogen exchange mechanisms were reported in recent ⁷¹Ga NMR studies on ligand-exchange reactions between GaX_4^- and GaY_4^- (X, Y = Cl, Br, I). The ⁷¹Ga chemical shifts for all possible four-coordinate gallates GaX_4^- (X = Cl, Br, I) and mixed-halide species GaX_nY_{4-n} (X, Y = Cl, Br, I) were found.¹⁸ Note that the low frequency shift with increasing number of iodine substituents is also due to SO effects.¹⁹ The impurity at $\delta = -312$ in the ³¹P NMR spectra of reaction 3 may be attributed to the resonance of PBrI₃⁺GaBr₄⁻.

The ³¹P NMR chemical shift of $\delta = -456$ found for $PI_4^+AlCl_4^-$ (Fig. 4, Table 5, reaction 4) is at lower frequency, as compared to $PI_4^+EX_4^-$ (E = Al, Ga; X = Br, I). This suggests that the PI_4^+ cation in $PI_4^+AlCl_4^-$ has a more isolated character and smaller I ··· Cl interactions in the solid-state, which is in agreement with the crystal structure.

Reaction products containing mixtures of PBr_n**I**_{4-n}⁺. Density functional calculations of the ³¹P chemical shifts in isolated PBr_n**I**_{4-n}⁺ (Table 6, Fig. 7) show the significant influence of SO effects. While the non-relativistic calculations would predict a slight increase in δ ³¹P from PBr₄⁺ through PI₄⁺, SO

contributions increase from δ -205 to -734 and thus are responsible for the observed large low frequency shifts upon increasing substitution by iodine.⁶ Based on these computational results for the isolated cations, we assigned the experimentally observed resonances found in the ³¹P NMR spectra of the solids formed by reactions 5 to 8.

Products from reactions 5 and 6 are clearly mixtures of PBr₄⁺ and PBr₃I⁺ species (PBr₄⁺AsF₆⁻: $\delta = -83$; PBr₄⁺SbF₆⁻: $\delta = -81$; PBr₃I⁺AsF₆⁻: $\delta = -195$; PBr₃I⁺SbF₆⁻: $\delta = -196$). A small amount of formed PBr₂I₂⁺AsF₆⁻ could be detected as a broad resonance at $\delta = -315$ in the ³¹P MAS NMR spectrum of reaction 5 (Table 5). An additional peak at $\delta = -33$ in the ³¹P MAS NMR spectrum of reaction 6 corresponds with literature values of the ³¹P chemical shift for the PF₄⁺ cation and indicates that a partial fluorination at phosphorus has obviously occurred during the reaction.^{1c}

The ³¹P MAS NMR spectrum of the solid yielded by the PBr₃/IBr/AlBr₃ reaction system (reaction 7) at 30 kHz (Fig. 8, Table 5) indicates the existence of all considered mixed bromoiodophosphonium complexes. The main signal at $\delta = -79$ can be assigned as PBr₄⁺AlBr₄⁻. The two resonances found at $\delta = -167$ and -171 represent the ³¹P chemical shifts for PBr₃I⁺ species. The weak and broad lines at $\delta = -250$ and -331 can be allocated to the ³¹P MAS NMR chemical shifts for the PBr₂I₂⁺ and PBrI₃⁺ tetrabromoaluminate(III) salts, respectively.

The ³¹P MAS NMR spectrum of the solid obtained from reaction 8 (PBr₃/IBr/GaBr₃) at 30 kHz (Fig. 8, Table 5) indicates that in this mixture there are four, two and one resonances associated with the PBr₄⁺, PBr₃I⁺ and PBr₂I₂⁺ regions, respectively. This suggests that a similar halogen exchange as found for reaction 3 has occurred during the preparation. Besides the signal for PBr₄⁺GaBr₄⁻ at $\delta = -80$ three narrow lines appear at higher frequency which can be attributed to the signals of PBr₄⁺GaBr₃I⁻ ($\delta = -78$), PBr₄⁺GaBr₂I₂⁻ ($\delta = -74$ ppm), and PBr₄⁺GaBrI₃⁻ ($\delta = -68$). The ³¹P resonance at $\delta = -170$ displays the same value as assigned for PBr₃I⁺AlBr₄⁻ and can be

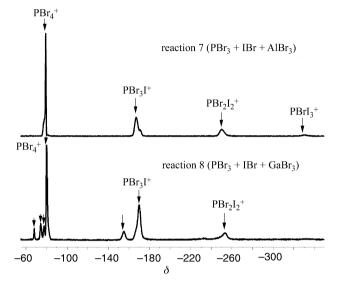

Fig. 8 MAS solid-state ³¹P NMR spectrum for reaction 7 (PBr₃/IBr/ AlBr₃) and reaction 8 (PBr₃/IBr/GaBr₃) at a spinning frequency of 30 kHz. The isotropic chemical shifts are indicated by arrows.

allocated to PBr₃I⁺GaBr₄⁻. The weaker resonance at $\delta = -153$ ppm may be attributed to PBr₃I⁺GaBr₃I⁻. The resonance at $\delta = -254$ is close to that observed for PBr₂I₂⁺AlBr₄⁻ and can be assigned to PBr₂I₂⁺GaBr₄⁻.

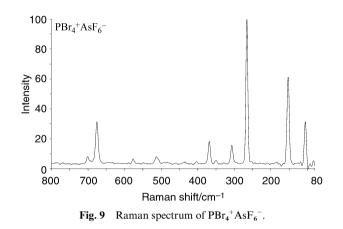

In most cases, the AsF₆⁻ and SbF₆⁻ salts are thought to be representative of "ideal" ionic species, whereas for EX₄⁻ (E = Al, Ga; X = Br, I) salts non-negligible interactions between complex cations and anions have to be considered. On average the low frequency shift from PBr₄⁺ to PI₄⁺ increases in intervals of roughly 85 ppm for AlBr₄⁻. In contrast, the increasing tendency to lower frequency of the ³¹P resonances of the AsF₆⁻ species from PBr₄⁺ to PBr₃I⁺ (112 ppm) and from PBr₃I⁺ to PBr₂I₂⁺ (120 ppm) is significantly higher.

Vibrational spectroscopy

 $\mathbf{PBr_4}^+\mathbf{AsF_6}^-$. The Raman spectrum of $\mathbf{PBr_4}^+\mathbf{AsF_6}^-$ is shown in Fig. 9. The vibrational frequencies and their assignment in comparison with $PBr_4^+EBr_4^-$ (E = Al, Ga) and the computed normal modes for PBr_4^+ are summarised in Table 7.^{4c} The frequencies of the PBr_4^+ cation are fairly consistent with literature values. The Raman-active symmetric v_1 (A₁) stretching mode of the PX_4^+ species is a characteristic frequency to indicate the extent of intermolecular cation ··· anion interactions. The v_1 (A₁) stretching mode at 266 cm⁻¹ in PBr₄⁺AsF₆⁻ is at considerably higher frequency than in $PBr_4^+EBr_4^-$ (E = Al: 256 cm⁻¹, Ga: 258 cm⁻¹).^{4c} This is consistent with the wellknown non-coordinating character of AsF6- anions, and with the expectation that no significant interactions between cations and anions occur for this system. A similar phenomenon is reported for the $(i-Pr)_3PI^+$ cation. The P–I stretching vibration of $(i-Pr)_3PI^+SbF_6^-$ at 157 cm⁻¹ is raised to higher wavenumbers than found in $(i-Pr)_3PI^+I^-(v(P-I): 150 \text{ cm}^{-1})$ and

in $(i-Pr)_3PI^+I_3^-$ (ν (P–I): 148 cm⁻¹), due to shorter P–I distances and less pronounced intermolecular interactions.²⁰

The IR spectrum of $PBr_4^+AsF_6^-$ shows two expected IR active modes, $v_3 (T_{1u})$ and $v_4 (T_{1u})$, at 697 and 391 cm⁻¹ for a free AsF_6^- anion, which are consistent with literature values.²¹ The Raman active $v_1 (A_{1g})$, $v_2 (E_g)$ and $v_5 (T_{2g})$ modes for AsF_6^- were observed at 675, 577 and 368 cm⁻¹. The appearance of two absorptions at 676 and 580 cm⁻¹ in the IR spectrum of PBr_4^+AsF_6^-, which can be assigned to the $v_1 (A_{1g})$ and $v_2 (E_g)$ modes of AsF_6^- is the conclusion that the octahedral symmetry of the anion in PBr_4^+AsF_6^- may be slightly distorted.

 $PI_4^+EBr_4^-$ (E = Al, Ga). The solid-state Raman spectra of $PI_4^+EBr_4^-$ (E = Al, Ga) and $PI_4^+AlCl_4^-$ are shown in Fig. 10. The computed and experimentally observed vibrational frequencies and their assignments are summarised in Table 8 in comparison with the vibrational frequencies found for $PI_4^+EI_4^-$ (E = Al, Ga) and $PI_4^+MF_6^-$ (M = As, Sb).

The symmetric v_1 (A₁) stretching mode for the anions in $PI_4^+EBr_4^-$ (E = Al, Ga) can be observed as the most intense peaks in the Raman spectra at 165 (E = Al) and 163 cm⁻¹ (E = Ga), respectively. When compared with the vibrational spectra of $PI_4^+EI_4^-$ (E = Al, Ga), the v_1 (A₁) stretching mode is significantly shifted to higher frequencies (12–14 cm⁻¹). In contrast to these results, the v_1 (A₁) stretching mode was found close to 194 cm⁻¹ in $PI_4^+MF_6^-$ (M = As, Sb).⁵ This appears consistent with the suggestion that the vibration frequencies should be at lower wavenumbers, because the P–I bond order in the compounds $PI_4^+EBr_4^-$ (E = Al, Ga) is reduced by weak I \cdots Br cation \cdots anion interactions, whereas the PI_4^+ cation in $PI_4^+MF_6^-$ (M = As, Sb) is almost isolated.

The presence of the anions EBr_4^- (E = Al, Ga) is confirmed by the symmetric stretching mode, v_1 (A₁), at 210 cm⁻¹ (PI₄⁺AlBr₄⁻) and 207 cm⁻¹ (PI₄⁺GaBr₄⁻). They are consistent with literature values (v_1 (AlBr₄⁻): 212 cm⁻¹;²² v_1 (GaBr₄⁻): 210 cm⁻¹²³). The strong absorptions in the IR spectra at

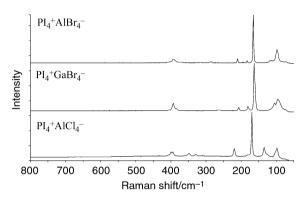

Fig. 10 Raman spectra of $PI_4^+AlBr_4^-$, $PI_4^+GaBr_4^-$ and $PI_4^+AlCl_4^-$.

393 cm⁻¹ (PI₄+AlBr₄⁻) and 263 cm⁻¹ (PI₄+GaBr₄⁻) can be assigned to the antisymmetric stretching mode, v_3 (T₂), of EBr₄⁻. Confirmed by the results of the ³¹P and ⁷¹Ga MAS NMR data, the sample of reaction 3 was a mixture of mostly PI₄+GaBr₄⁻ and small amounts of PI₄+EBr_nI_{4-n}⁻. Two intense bands at 278 and 240 cm⁻¹ in the IR spectrum of PI₄+GaBr₄⁻ can be assigned to stretching vibrations of the partially replaced GaBr₃I⁻ anion. Both Raman spectra of PI₄+EBr₄⁻ (E = Al, Ga) exhibit weak peaks at *ca*. 182 cm⁻¹ due to small I₂ impurities.

Consistent with the ³¹P MAS NMR results the experimentally observed symmetric P–I [v_1 (A₁)] stretching mode of the more isolated salt PI₄⁺AlCl₄⁻ at 169 cm⁻¹ appears at considerably higher wavenumbers than found in the complexes PI₄⁺EX₄⁻ (E = Al, Ga; X = Br, I). The Raman and IR frequencies at 496 (v_3), 350 (v_1), 219 (v_4) and 134 cm⁻¹ (v_2) agree with literature values^{2e} reported for the fundamental frequencies of AlCl₄⁻ and confirm the presence of this counteranion.

Reaction products containing mixtures of PBr_{*n*}**I**_{4-*n*}⁺. The solids formed from reactions 5 to 8 gave very complex IR and Raman spectra. Assignment of the fundamental frequencies of the mixed bromoiodophosphonium complexes is consequently very difficult. Besides the frequencies for PBr₄⁺, the fundamental modes for the anions AsF₆⁻ (reaction 5), SbF₆⁻ (reaction 6), AlBr₄⁻ (reaction 7) and GaBr₄⁻ (reaction 8) were found in the vibrational spectra. With respect to the computed vibrational frequencies and the results of the ³¹P MAS NMR data, we attempted to assign the fundamental frequencies of the PBr₃I⁺ cation in a reasonable way, as summarised in Table 9.

The Raman active stretching mode, v_1 (A₁), can be observed as intense peaks at 240 (AsF₆⁻, reaction 5), 237 (SbF₆⁻, reaction 6) and 222 (GaBr₄⁻, reaction 8) cm⁻¹ in the Raman spectra. As expected, significant increases in frequency occur for all modes of the PBr₃I⁺ cation on passing from complexes where tetrahaloaluminate and tetrahalogallate anions are present to those with the anions AsF₆⁻ and SbF₆⁻.

Conclusion

The solid-state ³¹P MAS NMR studies for PI₄⁺ species show extremely large negative ³¹P isotropic shifts ranging from $\delta = -295$ to -519. They depend considerably on the nature of the counter-ion. The more isolated the character of the PI_4^+ cation (shorter P-I bond lengths, weaker cation ··· anion interactions), the larger the P-I bond order becomes. Consequently, the Fermi-contact mechanism that transfers the spin-orbit induced spin density to the phosphorus nucleus is more efficient,¹⁷ and the ³¹P resonance is shifted to higher field.⁶ Significant donor-acceptor contacts between cation and anion in the solid-state lead to less pronounced low frequency isotropic ³¹P shifts. Additionally, a trend towards higher wavenumbers for the fundamental frequencies of PI_4^+ could be observed from the polymeric $[PI_4^+EI_4^- (E = AI, Ga)]$ to the "ideal" ionic cases $[PI_4^+MF_6^- (M = As, Sb)]$. For PBr_4^+ species these effects are less pronounced.

Based on the results of the computed isotropic ³¹P chemical shifts for isolated $PBr_nI_{4-n}^+$ cations, we found evidence for the existence of the hitherto unknown mixed bromoiodophosphonium cations PBr_3I^+ , $PBr_2I_2^+$ and $PBrI_3^+$ by means of solid-state ³¹P MAS NMR spectroscopy.

Due to increasing spin-orbit effects, the δ^{31} P shifts of the EBr₄⁻ salts (E = Al, Ga) move increasingly to low frequency along the series PBr₄⁺ < PBr₃I⁺ < PBr₂I₂⁺ < PBrI₃⁺ < PI₄⁺, in intervals of about 85 ppm. In the case of MF₆⁻ counter-anions (M = As, Sb), the corresponding increments to low frequency are significantly larger, due to the essentially isolated nature of the cations.

Experimental

General methods

All compounds reported here are moisture sensitive. Consequently, strictly anaerobic and anhydrous conditions were employed for their synthesis. Any subsequent manipulations were carried out inside a glove-box under dry nitrogen. AlBr₃, AlCl₃, Br₂, GaBr₃, IBr, ICl, I₂, PBr₃ and PI₃ (all Aldrich) were used as received. PBr₄⁺AlBr₄^{-,4c} PBr₄⁺GaBr₄^{-4c} and PI₄⁺GaI₄⁻⁶ were prepared according to the literature. The preparation of Br₃⁺AsF₆^{-,24} I₃⁺AsF₆⁻²⁵ and I₃⁺SbF₆⁻²⁶ also followed literature procedures. CFCl₃ and CS₂ were refluxed with P₄O₁₀ and distilled before used.

³¹P and ⁷¹Ga NMR spectra were measured at 202.49 and 152.48 MHz, respectively, with a BRUKER DSX AVANCE 500 FT NMR spectrometer under fast spinning conditions about the magic-angle (MAS). A standard double-bearing MAS probe designed for zirconia dioxide rotors (diameter: 2.5 mm) was used with spinning frequencies up to 30 kHz. For the ³¹P NMR measurements a single pulse acquisition was used and the 90° pulse length was adjusted to 2.0 μ s. The recycle delay was set to values between 5 and 60 s, depending on the spin lattice relaxation time, to ensure correct relative signal intensities.

For the ⁷¹Ga NMR measurements a 16-fold phase cycled Hahn echo sequence $(90^{\circ}-t_1-180^{\circ}-t_1-acquisition)$ was used. The interpulse distance t_1 was set to the inverse spinning frequency ($t_1 = 1/v_{rot} = 1/27$ kHz). The 90° (1.6 µs) and 180° (3.1 ns) pulses were adjusted to maximal signal intensity.

Due to fast spinning conditions ($v_{rot} > 20$ kHz), the recorded spectra contain only few spinning side bands which are clearly separated from the isotropic chemical shift resonances. Therefore, the values for the isotropic chemical shifts of the cations under study could be extracted directly from the spectra without simulations taking into account the chemical shift anisotropy. Overlapping signals were deconvoluted using a pseudo-Voigt profile. The samples were filled under a nitrogen atmosphere in a glove-box. The ³¹P spectra were referenced to

85% H₃PO₄ in CDCl₃, isotropic ⁷¹Ga chemical shifts to an external 1.0 M solution of Ga(NO₃)₃.

Raman spectra were obtained of powdered solid samples contained in glass capillary tubes with a Perkin-Elmer 2000 NIR spectrometer in the range $800-50 \text{ cm}^{-1}$. IR spectra were recorded on Nujol mulls between CsI plates in the range $800-200 \text{ cm}^{-1}$ on a Nicolet 520 FT IR spectrometer. For the determination of decomposition points, samples were heated in sealed glass capillaries in a Büchi B450 instrument.

Syntheses

Reaction 1: preparation of PBr_4^+AsF_6^-. PBr₃ (0.61 g, 2.25 mmol) was reacted with $Br_3^+AsF_6^-$ (0.97 g, 2.25 mmol) in CFCl₃ (15 mL) with stirring at room temperature in a twobulbed glass vessel incorporating a coarse sintered-glass frit and a Young valve. An intense brown solution of Br_2 over a colourless solid was obtained. After stirring for 2 h the solution was filtered. Solvent and traces of remaining Br_2 were removed under dynamic vacuum, leaving a colourless solid. Yield: 0.35 g (29%), mp 144–148 °C (decomp.).

Reaction 2: preparation of PI_4^+AlBr_4^-. PI_3 (0.41 g, 1.00 mmol) was reacted with IBr (0.20 g, 1.00 mmol) and AlBr₃ (0.27 g, 1.00 mmol) in CS₂ (20 mL) with stirring at room temperature. After stirring for 2 h the solvent was removed under dynamic vacuum, leaving a red solid. Yield: 0.82 g (93%), mp 109 °C (decomp.).

Reaction 3 (PI₃ + IBr + GaBr₃). PI₃ (0.41 g, 1.00 mmol) was reacted with IBr (0.20 g, 1.00 mmol) and GaBr₃ (0.31 g, 1.00 mmol) in CS₂ (20 mL) with stirring at room temperature. After stirring for 2 h the solvent were removed under dynamic vacuum, leaving a red solid. Yield: 0.79 g, mp 86 °C (decomp.).

Reaction 4: preparation of PI₄⁺AlCl₄⁻. PI₃ (0.82 g, 2.00 mmol) was reacted with ICl (0.32 g, 2.00 mmol) and AlCl₃ (0.27 g, 2.00 mmol) in CS₂ (30 mL) with stirring at room temperature. After stirring for 2 h the solvent and traces of ICl were removed at 50 °C under dynamic vacuum, leaving an orange solid. Yield: 0.97 g (69%), mp 70 °C (decomp.).

Reaction 5 (PBr₃ + I₃⁺AsF₆⁻). PBr₃ (0.27 g, 1.00 mmol) was reacted with $I_3^+AsF_6^-$ (0.57 g, 1.00 mmol) in CFCl₃ (15 mL) with stirring at room temperature in a two-bulbed glass vessel incorporating a coarse sintered-glass frit and a Young valve. An intense dark purple solution over a pale brownish solid was obtained. After stirring for 24 h the solution was filtered, and refiltered several times, by condensing about half the solvent back and refiltering. Solvent and traces of remaining I_2 were removed under dynamic vacuum, leaving a pale brownish solid. Yield: 0.31 g, mp 146 °C (decomp.).

Reaction 6 (PBr₃ + I₃+SbF₆⁻). PBr₃ (1.04 g, 3.84 mmol) was reacted with $I_3+SbF_6^-$ (2.37 g, 3.84 mmol) in CFCl₃ (20 mL) with stirring at room temperature in a two-bulbed glass vessel incorporating a coarse sintered-glass frit and a Young valve. An intense dark purple solution over a pale brownish solid was obtained. After stirring for 24 h the solution was filtered, and refiltered several times, by condensing about half the solvent back and refiltering. Solvent and traces of remaining I_2 were removed under dynamic vacuum, leaving a pale brownish solid. Yield: 1.25 g, mp 90 °C (decomp.).

Reaction 7 (PBr₃ + IBr + AlBr₃). PBr₃ (0.27 g, 1.00 mmol) was reacted with IBr (0.20 g, 1.00 mmol) and AlBr₃ (0.27 g, 1.00 mmol) in CS₂ (20 mL) with stirring at room temperature. After stirring for 2 h the solvent was removed under dynamic vacuum, leaving a brown solid. Yield: 0.51 g, mp 97 °C (decomp.).

Reaction 8 (PBr₃ + IBr + GaBr₃). PBr₃ (0.27 g, 1.00 mmol) was reacted with IBr (0.20 g, 1.00 mmol) and AlBr₃ (0.31 g, 1.00 mmol) in CS₂ (20 mL) with stirring at room temperature. After stirring for 2 h the solvent was removed under dynamic vacuum, leaving an orange solid. Yield: 0.59 g, mp 67–69 °C (decomp.).

Crystallography

Single crystals of $PI_4^+AlCI_4^-$, $PI_4^+AlBr_4^-$ and $PI_4^+GaI_4^-$ suitable for X-ray structure determination were grown from CS_2 and covered with perfluoropolyether oil. The selected crystals were mounted on the tip of a glass fibre and placed on a goniometer head.

Crystal data for $PI_4^+AICI_4^-$. Al CI_4I_4P , M = 707.35, monoclinic, a = 6.523(6), b = 15.81(1), c = 14.34(1) Å, $\beta = 92.09(1)^\circ$, U = 1478(2) Å³, T = 193(2) K, space group $P2_1/c$, Z = 4. Siemens CCD area detector, scan type: hemisphere, μ (Mo-K α , $\lambda = 0.71073$ Å) = 9.277 mm⁻¹, reflections collected: 5309, independent reflections: 1627 ($R_{int} = 0.0308$), observed reflections: 1292 [$F > 4\sigma(F)$]. Absorption correction: SADABS.²⁷ Structure solution and refinement program: SHELXL-97,²⁸ direct methods, final R indices for all atoms in anisotropic description [$F > 4\sigma(F)$]: R1 = 0.0440, wR2 = 0.1023, R1 =0.0613, wR2 = 0.1099 (all data).

Crystal data for PI₄⁺AlBr₄⁻. AlBr₄I₄P, M = 885.19, monoclinic, a = 6.6475(8), b = 16.471(2), c = 14.534(4) Å, $\beta = 91.832(2)^\circ$, U = 1590.5(3) Å³, T = 188(2) K, space group $P2_1/c$, Z = 4. Siemens CCD area detector, scan type: hemisphere, μ (Mo-K α , $\lambda = 0.71073$ Å) = 17.996 mm⁻¹, reflections collected: 6541, independent reflections: 2056 ($R_{int} = 0.0374$), observed reflections: 1673 [$F > 4\sigma(F$]]. Absorption correction: SADABS.²⁷ Structure solution and refinement program: SHELXL-97,²⁸ direct methods, final *R* indices for all atoms in anisotropic description [$F > 4\sigma(F$]]: R1 = 0.0447, wR2 = 0.1080, R1 = 0.0580, wR2 = 0.1145 (all data).

Crystal data for PI₄⁺GaI₄⁻. GaI₈P, M = 1115.89, orthorhombic, a = 11.0101(7), b = 10.4007(7), c = 15.1835(9) Å, U = 1738.7(2) Å³, T = 200(2) K, space group $Pna2_1$, Z = 4. Stoe IPDS diffractometer, μ (Mo-K α , $\lambda = 0.71073$ Å) = 15.839 mm⁻¹, reflections collected: 9490, independent reflections: 3879 ($R_{int} = 0.0257$), observed reflections: 3142 [$F > 2\sigma(I$]]. Absorption correction: numerical. Structure solution and refinement program: SHELXL-97,²⁸ direct methods, final *R* indices for all atoms in anisotropic description [$F > 2\sigma(I$]]: R1 = 0.0377, wR2 = 0.0758, R1 = 0.0516, wR2 = 0.0785 (all data).

Computational methods

The structures of the isolated $PBr_nI_{4-n}^+$ ($0 \le n \le 4$) were optimised at the second-order Møller–Plesset (MP2) level with the program package Gaussian 98.²⁹ Quasirelativistic pseudopotentials and DZP valence basis sets were employed for P, I, and Br.³⁰ All species were characterised as minima by harmonic vibrational frequency analysis.³¹ It should be noted that the calculations were performed on isolated (gas-phase) cations. There may well be significant differences between gas-phase and solid-state data.

The DFT calculations of ³¹P chemical shifts were carried out at the same theoretical level as in ref. 6. The initial, non-relativistic nuclear shielding calculations (uncorrected for spin–orbit coupling) used the sum-over-states density functional perturbation theory approach (SOS-DFPT),^{32,33} with individual gauges for localised orbitals (IGLO³⁴). The

88 (0)	. /					. /		v_5 (E, PBr ₃ I ⁺)

¹ IR intensity [km mol⁻¹] in parentheses. ^b The Raman spectrum of the product showed fluorescence and therefore no Raman data was available.

underlying Kohn–Sham calculations employed the gradientcorrected PW91³⁵ exchange-correlation functional. All calculations were carried out with the deMon-KS³⁶ and deMon-NMR³² codes.

IGLO-II all-electron basis sets³⁴ were used on all atoms (omitting f-functions on iodine due to program limitations), with density and exchange-correlation potential fitting auxiliary basis sets of the sizes 5,4 (P) and 5,5 (Br, I) (*n,m* denotes *n* s-functions and *m* spd-shells with shared exponents³⁶). All six Cartesian components of d-basis functions were kept. The IGLO procedure³⁴ employed the Boys localisation scheme.³⁷ For comparison to experiment, the computed absolute shieldings σ were converted to relative shifts δ *via* the absolute shielding value of 328.4 ppm for 85% H₃PO₄ given by Jameson *et al.*³⁸

Spin-orbit corrections to the nuclear shieldings were computed separately by the combined finite-perturbation/ SOS-DFPT ansatz of ref. 32. A recently implemented and validated ³⁹ mean field approximation was used to compute the one- and two-electron SO integrals. An IGLO choice of gauge origin has been used in the calculation of the SO corrections. The calculations of the spin-orbit corrections used the same basis sets described above, but the spherical d-basis functions were projected out for compatibility with the SO integral code. 64 points of radial quadrature and the PP86 functional⁴⁰ were employed. The initial finite perturbation (with a perturbation parameter $\lambda = 10^{-5}$ arbitrary units) was chosen to be the nuclear magnetic moment of the phosphorus nucleus.

Acknowledgements

We gratefully acknowledge the support of the Fonds der Chemischen Industrie and the University of Munich. In addition we would like to thank Prof. Peter N. Gates and Prof. Günther Engelhardt, Dr Axel Schulz and Dipl.-Chem. Gernot Kramer for valuable discussions and Andrea Barra for NMR spectroscopic measurements. M.K. is grateful to Deutsche Forschungsgemeinschaft for support (Schwerpunktprogramm "Relativistische Effekte") and thanks Dr Vladimir G. Malkin and Dr Olga L. Malkina for helpful discussions.
