Summary
Aim: PankoMab is a novel antibody that recognizes a tumor-specific epitope of Mucin 1 (MUC1). The aim of this study was the evaluation of PankoMab as a potential diagnostic tool and its comparison with two established antibodies against MUC1 in human ductal breast cancer.

Materials and Methods: Breast carcinomas were obtained from 82 patients. MUC1 expression and hormone receptor status were determined by immunohistochemistry of paraffin-embedded material. Results: PankoMab revealed strong correlation to hormone receptor expression. DF3 showed no correlation with grading, lymph node involvement and/or estrogen receptor (ER) expression. In the subgroup of lymph node-positive and ER-negative tumors, we saw a significantly reduced DF3 staining in G3 tumors compared to G2 tumors. VU-4-H5 showed increased staining intensity in correlation with increased grading. In addition, we also identified a significantly higher expression of the VU-4-H5 epitope in lymph node-positive carcinomas compared to carcinomas without lymph node involvement. Conclusion: PankoMab revealed strong correlation to hormone receptor expression in ductal carcinoma of the breast. VU-4-H5 showed increased staining intensity in correlation with increased grading and lymph node involvement. PankoMab and VU-4-H5 staining could be a useful combination in ductal breast cancer prognosis by immunohistochemistry.

Zusammenfassung
Hintergrund: PankoMab ist ein neuer Antikörper, der ein tumorspezifisches Epitop von Mucin 1 (MUC1) erkennt. Ziel der Arbeit war es, PankoMab als diagnostischen Antikörper beim Mammakarzinom zu evaluieren und mit zwei etablierten Antikörpern gegen MUC1 zu vergleichen.

Material und Methoden: Mammakarzinomgewebe von 82 Patientinnen wurde entsprechend den aktuellen internationalen Standards klassifiziert. MUC1-Expression und Hormonrezeptorstatus wurden immunhistochemisch an Paraffinblöcken bestimmt.

Schlussfolgerungen: PankoMab wurde zur Erkennung von MUC1 in Tumoren entwickelt. In dieser Studie zeigte PankoMab eine hohe Korrelation mit der Hormonrezeptorexpression beim duktaLEN Mammakarzinom. VU-4-H5 zeigt steigende Färbungsintensität in Korrelation mit steigendem Grading und Lymphknotenbefall. PankoMab- und VU-4-H5-Färbung könnten eine sinnvolle Kombination zur Prognosebestimmung des Mammakarzinoms sein.
Mucin derives from the word mucus and designates the structural component of it. The O-glycans exhibit high water-binding capacity on the mucins, protect the central protein from proteolysis and are involved in antigen binding and/or signal transduction [1, 2]. Mucins are divided into two groups: membrane-bound mucins such as Mucin 1 (MUC1) and secreted mucins.

MUC1 (also named CD227, EMA, PAS-O, PEM, MAM-6, or episialin) plays a role in the barrier function of the mucous membranes and helps to regulate cell adhesion. The chromosomal localization was defined as 1q21 [3]. It is a high-molecular-weight transmembrane glycoprotein with unique properties. It is extremely long and its stretched extracellular part consists of identical repeats of a 20-amino-acid peptide, the number of which varies in the population. The repeats are heavily O-glycosylated, with characteristic short glycan chains. This can be monitored directly with monoclonal antibodies (mAbs) to the glycans as well as indirectly with mAbs to peptide epitopes, because their binding is often hindered by the glycans [4].

Cancer cells, especially adenocarcinomas, express aberrant forms and amounts of mucins [5–7]. The expression of distinct exposed oligosaccharide structures confers on tumor cells an enormous range of potential ligands for interaction with other receptors at the cell surface [8, 9]. An increased and often depolarized expression throughout the entire cell cytoplasm has been recorded [10]. It is generally believed that MUC1 overexpression by tumor cells facilitates invasive growth and metastasis [11, 12]. It was also thought that overexpression of MUC1 disrupts cell-cell and cell-extracellular matrix adhesions [13–15].

In addition, MUC1 was shown to contribute to cancer cell escape from immune surveillance as MUC1-expressing cells are less susceptible to T-cell- and NK cell-mediated lysis [16]. On the other hand, absence of MUC1 expression also occurred and was associated with the absence of estrogen receptors (ERs) and progesterone receptors (PRs) in several breast cancer studies. These findings support the observation by Luna-More et al. [17] that tumors of the human breast negative for MUC1 are high-grade, are ER and PR negative and associated with positive axillary lymph nodes. Other studies also related low or negative MUC1 expression to higher tumor grade and poor prognosis [18, 19].

PankoMab is a novel antibody that binds specifically to tumor MUC1. Therefore, the aim of this study was, firstly, to evaluate the new mAb, PankoMab, as a diagnostic tool in ductal invasive breast cancer, secondly, to compare this antibody with the established antibodies DF3 and VU-4-H5 and, thirdly, to correlate all these three antibodies with prognostic parameters (lymph node involvement, grading, and hormone receptor expression).

### Patients and Methods

#### Patients

Ductal breast carcinomas were obtained from 82 patients and classified according to current international standards. Tumor, node, metastasis (TNM) classification was done according to the World Health Organization (WHO) system [20]. The histological grading classification was determined according to a modification of the Elston and Ellis grading proposed by Bloom and Richardson [21]. The hormone receptor status was determined by immunohistochemistry on paraffin-embedded material. The immunoreactive score (IRS) was assigned according to Remmele and Stegner [22]. Cells were regarded as hormone receptor positive when there was a positive staining in ≥ 10% of the tumor cell nuclei (see online supplemental material).

#### Immunohistochemistry

Immunohistochemistry was performed using a combination of pressure cooker heating and the standard streptavidin-biotin-peroxidase complex with the use of the mouse IgG-Vectastain Elite ABC kit (Vector Laboratories, Burlingame, CA, USA). The mouse mAbs used for these experiments are listed in table 2.

Paraffin-embedded tissue sections were dewaxed using xylene for 15 min, rehydrated in a descending series of alcohol (100, 96 and 70%), and subjected to epitope retrieval for 10 min in a pressure cooker using sodium citrate buffer (pH 6.0) containing 0.1 M citric acid and 0.1 M sodium citrate in distilled water. After cooling, sections were washed twice in PBS. Endogenous peroxidase activity was blocked by immersion in 3% hydrogen peroxide (Merck, Darmstadt, Germany) in methanol for 20 min. Non-specific binding of the primary antibodies was blocked by incubating the sections with diluted normal serum (10 ml PBS containing 150 μl horse serum; Vector Laboratories) for 20 min at room temperature. The sections were then incubated at room temperature for 60 min with the primary antibodies. After washing with PBS, the sections were incubated in diluted biotinylated serum (10 ml PBS containing 50 μl horse serum; Vector Laboratories) for 30 min at room temperature. After incubation with the avidin-biotin-peroxidase complex (diluted in 10 ml PBS; Vector Laboratories) for 30 min and repeated washing steps with PBS, visualization was performed with substrate and the chromogenic compound 3,3′-diaminobenzidine (DAB; Dako, Glostrup, Denmark) for 8–10 min. Sections were counterstained with Mayer’s acidic hematoxylin and dehydrated in an ascending series of alcohol (70–100%). After xylol treatment, the sections were covered. Negative controls were performed by replacing the primary antibody with normal horse serum.

For specificity control, MUC1 antibodies were incubated with 300 U/ml MUC1-positive control reagent (Tosoh, Tokyo, Japan) and applied to the breast cancer tissue slides. Reduced MUC1 staining in (b) was observed for DF3 and VU-4-H5. PankoMab is highly specific for non-shed MUC1. PankoMab staining cannot be reduced with the Tosoh control reagent which represents a soluble and shed form of the MUC1 antigen.

Immunohistochemical staining was performed using an appropriate positive control. Positive cells showed a brownish color, and negative controls, as well as unstained cells, were blue.

The intensity and distribution patterns of specific immunohistochemical staining were evaluated using the semi-quantitative assay as described elsewhere, and used to assess the expression pattern of various marker molecules like steroid receptors, glycoendin and MUC1 [23–25]. The IRS score was calculated by multiplication of the optical staining intensity (graded as 0 = no, 1 = weak, 2 = moderate and 3 = strong staining) and the percentage of positively stained cells (0 = no staining, 1 = <10% of cells, 2 = 11–50% of cells, 3 = 51–80% of cells and 4 = >81% of cells stained). The slides were examined by two independent observers. Sections were examined using a CCD color camera (JVC, Victor Company of Japan, Japan) and a Leitz (Wetzlar, Germany) microscope.

**Results**

The staining results in the ductal breast carcinomas of all 82 patients are shown in table 1.

**PankoMab**

Expression of MUC1 as analyzed with the PankoMab antibody (n = 82, all analyzable) was down-regulated with increased grading. Highest values were measured in G1 and lowest in G3 tumors, although without statistical significance. In addition, there were no differences in MUC1 staining with the PankoMab antibody in invasive ductal carcinomas with or without lymph node metastasis.

However, significant differences in MUC1 staining were found in ER-positive and -negative ductal carcinomas. ER-negative carcinomas showed significantly reduced staining of MUC1 (fig. 2a; p = 0.0047) compared to ER-positive carcinomas (fig. 2b). A quantitative summary of the staining results is presented in fig. 2c. The results of linear regression using a GLM are shown in table 3.

**DF3**

Although the investigation of MUC1 staining with the DF3 antibody (n = 81; 1 not analyzable) showed no significant correlation with any of the three prognostic parameters (table 3), we were able to detect significant differences in one subgroup. Invasive ductal carcinomas with lymph node metastasis and lack of expression of ER revealed significant differences (p = 0.046) in DF3 staining in G2 compared to G3 tumors. G2 tumors showed very strong expression of MUC1 (fig. 3a) and G3 tumors showed only weak expression of MUC1 (fig. 3b) when analyzed with the antibody DF3. A quantitative summary of this staining result is presented in fig 3c. The results of linear regression are shown in table 3.

**VU-4-H5**

Using the VU-4-H5 antibody (n = 79; 3 not analyzable), we could demonstrate a significant correlation with lymph node involvement and grading, but not with the receptor status, by comparing all cases (table 3). In addition, we also found significant differences in one specific subgroup. In ductal carcinomas without lymph node metastasis and no expression of ER, VU-4-H5 staining in G2 tumors was significantly lower.

Fig. 2. ER-negative carcinomas showed significantly reduced staining with Pankomab (a) (p = 0.0047) compared to ER-positive carcinomas (b). A semi-quantitative evaluation of the staining results is presented in a box plot in (c) (n = 82; ER neg. n = 34, ER pos. n = 48). The boxes represent the range between the 25th and 75th percentiles with a horizontal line at the median. The bars delineate the 5th and 95th percentiles. The IRS score is illustrated on the y-axis.

Fig. 3. G2 tumors showed very strong expression of MUC1 (a) and G3 tumors faint expression of MUC1 (b) analyzed with the antibody DF3. A semi-quantitative evaluation of this staining is presented in a box plot in (c) (n = 20; G2 N+ ER– n = 10, G3 N+ ER– n = 10). The boxes represent the range between the 25th and 75th percentiles with a horizontal line at the median. The bars delineate the 5th and 95th percentiles. The circles indicate values more than 1.5 box lengths. The IRS score is illustrated on the y-axis.

(fig. 4a) compared to G3 (fig. 4b) tumors (p = 0.008). In addition, in ductal carcinomas with lymph node metastasis and expression of ER, increased VU-4-H5 staining from G2 (fig. 4c) to G3 (fig. 4d) tumors was observed, without reaching statistical significance. In contrast to Pankomab and DF3 staining, VU-4-H5 staining was increased from G1 to G3 carcinomas (fig. 4e) and from lymph node-negative to lymph node-positive tumors (fig. 4f). Linear regression results are shown in table 3.

The results of the multivariate logistic regression analysis to correlate MUC1 and VU-4-H5 simultaneously are shown in table 4.

*Cumulative logit model.

Fig. 4. VU-4-H5 staining in G2 tumors was significantly lower (a) compared to G3 (b) tumors. In ductal carcinomas with lymph node metastasis and expression of ER, increased VU-4-H5 staining from G2 (e) to G3 (d) tumors was observed. VU-4-H5 expression was increased from G1 to G3 carcinomas (e) (n = 79; G1 n = 9, G2 n = 38, G3 n = 32) and from lymph node-negative to lymph node-positive tumors (f) (n = 79; LN- 42, LN+ 37). The boxes represent the range between the 25th and 75th percentiles with a horizontal line at the median. The bars delineate the 5th and 95th percentiles. The circle indicates values more than 1.5 box lengths. The IRS score is illustrated on the y-axis.

Discussion

In this study, we investigated a novel anti-MUC1 antibody called PankoMab as a potential new diagnostic tool and compared its ability to define prognostically relevant groups of patients with two established antibodies (DF3 and VU-4-H5) nominally directed against the same antigen. In detail, we examined the relationship between MUC1 expression patterns as seen by the three antibodies in invasive ductal carcinoma of the breast and established tumor characteristics like lymph node involvement, hormone receptor status, and grading. To avoid ambiguous results due to the heterogeneity of breast cancer, we focused on invasive ductal carcinomas, the most common type of breast cancer.

All three anti-MUC1 antibodies were of the same isotype (mouse IgG1). The antibody DF3 was first described in 1984 by Kufe et al. [38]. It was generated with a membrane fraction of breast cancer tissue as immunogen. DF3 is part of the CA15-3 sandwich assay for serum MUC1 [26]. The antibody VU-4-H5 was generated with a synthetic MUC1 peptide consisting of three tandem repeats as immunogen. Both antibodies, DF3 and VU-4-H5, were evaluated during the ISOBM TD-4 International Workshop on Monoclonal Antibodies against MUC1 [27]. As a result of this Workshop, they were confirmed in their MUC1 specificity, and the epitope sequence was determined as APDTRPAP for both antibodies. Nonetheless, the fine specificities were not identical. In immunohistochemistry, DF3 did react with normal gastrointestinal and breast tissues without pretreatment whereas VU-4-H5 became positive with normal tissues only after partial deglycosylation by periodate oxidation. In addition, the cellular localization of the antigen analyzed with a MUC1-positive tumor cell line was different [4]. Besides aberrant expression of fully glycosylated MUC1, expression of underglycosylated MUC1 is often found in human carcinomas [28–30]; VU-4-H5 is directed against the core peptide of MUC1 and stains positive only when the MUC1 molecule is underglycosylated, presenting simpler and fewer carbohydrate chains [12, 31].

PankoMab [32] is a novel MUC1 antibody explicitly tailored to recognize a tumor-associated MUC1 epitope (TAMUC1) described earlier [33, 34]. This epitope consists of a special carbohydrate-induced conformation of the PDTRP motif. PankoMab has improved tumor selectivity, making it very attractive as a potential therapeutic antibody.

In the present study, we demonstrate that PankoMab may also be suited as a diagnostic antibody. In contrast to the antibodies DF3 and VU-4-H5, PankoMab reactivity revealed a strong correlation with the expression of the ER. No correlation to lymph node involvement was found; however, in our study, the localization of the antigen (membrane versus cytoplasm) was not considered [17]. DF3 showed no correlation with grading, lymph node involvement or ER expression. Only in one subgroup of lymph node-positive, ER-negative tumors, we found significantly reduced DF3 staining in G3 compared to G2 tumors. VU-4-H5 showed increased staining intensity in correlation with increased grading and lymph node involvement, a result in contrast to the data of Luna-More [17], which were obtained with another anti-MUC1 antibody (E29) and considered the cellular distribution of the antigen.
Because VU-4-H5 detects MUC1 with less glycosylated sugar chains and as glycosylation of mucins is often reduced with tumor progression [35–37], our results on VU-4-H5 staining are in concordance with these findings.

In conclusion, PankoMab is a novel anti-MUC1 antibody with diagnostic potential providing strong correlation with ER expression, a property not shown by the two established anti-MUC1 antibodies used for comparison. Its use in combination with VU-4-H5 may be an alternative option in comparison with the established DF3 antibody, which showed no correlation with grading or hormone receptor status.

**Table 1.** PankoMab, DF3 and VU-4-H5 staining in ductal breast carcinomas of 82 patients
