Hypocholesterolemia, which often accompanies infectious diseases has been suggested to serve as a prognostic marker in hospitalized patients. Even though patients with chemotherapy-induced leukopenia are at high risk of infection and mortality, only limited information is available on serum cholesterol levels in these patients. We therefore measured serum cholesterol levels in 17 patients with hematological malignancies during chemotherapy-induced neutropenia and correlated it with clinical outcome. Patients with fever (³38.5 °C) showed a significant decrease in serum cholesterol levels within 24 hours. Eight days after onset of the fever non-survivors had significantly lower serum cholesterol levels (median 2.09 mmol/l, range 0.49–2.79, n=6) compared to survivors (median 3.23 mmol/l, range 1.68–4.86, n=11). Cholesterol levels in survivors returned to baseline levels at the time of discharge from the hospital. At the onset of fever, serum levels of inflammatory cytokines interleukin-6, tumor necrosis factor (TNF) and soluble TNF receptors p55 and p75 were elevated in all patients, but only TNF and TNF receptor p75 levels were significantly different in survivors and non-survivors.

Our data suggest that a decrease in serum cholesterol levels is a prognostic marker in neutropenic patients with fever. Release of inflammatory cytokines may in part be responsible for hypocholesterolemia in these patients. Clin Chem Lab Med 2002; 40(3):304–307

Key words: Cholesterol; Neutropenic; Fever; Sepsis; Interleukin-6 (IL-6); Tumor necrosis factor (TNF). Abbreviations: CRP, C-reactive protein; FUO, fever of unknown origin; IL, interleukin; NHL, non-Hodgkin lymphoma; sTNF-R, soluble TNF receptor; TNF, tumor necrosis factor; WBC, white blood count.

Introduction

A reduction in serum cholesterol levels during the acute phase response to various conditions such as infection (1–3), surgery (4), burn injury (5), sepsis and multiorgan failure (6) has been described in humans. The degree of hypocholesterolemia under these conditions may reflect the severity of disease. In addition, numerous recent studies indicate that low cholesterol levels are associated with increased mortality (6–8). In a large population of hospitalized patients prognostic value of serum cholesterol has been reported irrespective of the underlying disease (9).

Patients with chemotherapy-induced neutropenia are at high risk of bacterial infectious disease and frequently develop fever which may lead to mortality (10). Even though cytokine levels were elevated in these patients and increased interleukin-6 (IL-6) levels determined the mortality (11), no data on serum cholesterol levels are available. In order to examine the prognostic value of cholesterol concentration, we measured its serum levels in neutropenic patients at the time of onset of fever in response to infection and correlated these levels with clinical outcome. Although the underlying mechanism for low serum cholesterol levels in inflammatory conditions is still unclear, studies in experimental animals suggest that cytokines which are released during inflammation modulate lipoprotein metabolism. It has also been reported that infusion of IL-1 and tumor necrosis factor (TNF) (12–14) in experimental animals, as well as TNF (15), IL-2 (16), IL-6 (17) in cancer patients, diminishes plasma cholesterol levels. This suggests that cytokines may in part be responsible for the hypocholesterolemia. We therefore measured serum levels of IL-6, TNF and soluble TNF receptors (sTNF-R) in order to establish whether circulating levels of these proinflammatory cytokines correlate with serum cholesterol levels.

Patients, Materials and Methods

Patients and blood sampling

Patients with the following oncological diagnoses were included in the study: 11 with acute myeloid leukemia, 2 with acute lymphocytic leukemia, 2 with chronic myeloid leukemia, 1 with non-Hodgkin lymphoma (NHL) and 1 with testicular cancer. All patients undergoing intensive chemotherapy developed severe leukopenia (white blood count (WBC) <1 x 10⁹/l). Clinical course was followed by daily monitoring of fever, the signs of infection (e.g. blood cultures), medication (antibiotics, transfusion) and clinical chemistry parameters (WBC, hemoglobin and C-reactive protein (CRP)). Patients were included in the study at the onset of fever >38.5 °C which was unrelated to changes in transfusion or drug therapy and were followed for 1 week. Cholesterol was measured at the onset of fever and subsequently on day 2, 4, 8 and at discharge. Cholesterol values prior to chemotherapy were obtained from hospital charts. Aliquots of serum obtained at the
onset of fever were stored at –70 °C for the measurement of cytokines. In addition, blood samples were collected from six healthy volunteers who showed no signs of fever or infection and had normal WBC.

**Analytical techniques**

Serum levels of cholesterol and triglycerides were measured with Hitachi automated system (Boehringer Mannheim, Mannheim, Germany). Serum TNF and IL-6 levels were measured with a commercial enzyme-linked immunosorbent assay (Biosource Europe, Nivelles, Belgium). Both assays have a detection limit of <3 pg/ml. sTNF-R p55 and p75 were measured automatically on CobasCore with enzyme-linked immunobinding assays (Hoffmann La Roche Ltd., Basel Switzerland). The receptor assay has a detection limit of 100 pg/ml and is not affected by the presence of free or unbound TNF at a concentration below 10 ng/ml (18).

**Statistics**

Values for lipid and cytokine measurements are given as median and range. Statistical significance was calculated using Mann-Whitney-Wilcoxon-test test and a p-value <0.05 was considered significant.

**Results**

Eleven out of 17 patients included in this study showed positive blood cultures. Pathogens included *Staphylococcus aureus* (n=3), *Streptococcus spp* (n=4), *Enterococcus faecalis* (n=1), *Pseudomonas aeruginosa* (n=1) and *Candida albicans* (n=2). In the remaining six patients blood cultures were negative. Three of these patients developed clinical and radiological signs of bilateral pneumonia without the presence of bacterial or fungal pathogens either at the time of first symptoms or during ventilation. In the remaining three patients fever was classified as fever of unknown origin (FUO) (Table 1).

Values are given as median (range), ns=not significant.

Onset of fever during chemotherapy-induced neutropenia significantly decreased median serum cholesterol levels from 4.58 mmol/l (range 3.10–6.54) to 3.00 mmol/l (range 1.73–4.50) (Figure 1). Cholesterol levels in all patients showed a tendency to decrease further on the second (median 2.64 mmol/l, range 1.66–3.49) and fourth day (median 2.59 mmol/l, range 0.49–2.79). However, these changes were statistically not significant. Cholesterol levels in non-survivors were significantly higher (p<0.05) on day 2, 4 and 8 (3.13 mmol/l, range 1.66–3.16) and 2.10 mmol/l (range 0.49–2.79), respectively. In eleven survivors cholesterol levels were significantly higher (p<0.05) on day 2, 4 and 8 (3.13 mmol/l, range 1.76–3.49, 2.79 mmol/l, range 1.68–3.91 and 3.23 mmol/l, range 1.68–4.86; respectively) and returned to nearly baseline values of 4.68 mmol/l (range 3.08–8.15) at the time of discharge (Figure 2).

At the onset of fever, median serum levels of IL-6, TNF and sTNF-R were significantly higher in the patients compared to healthy controls (IL-6: 230 pg/ml (range 8–1000) vs. 3 pg/ml (range 3–11); TNF: 19 pg/ml (range 3–84) vs. 12 pg/ml (range 8–26); sTNF-R p55: 2.6 ng/ml (range 1.4–13.4) vs. 1.8 ng/ml (range 0.8–2.4); sTNF-R p75: 7.0 ng/ml (range 2.4–21.0) vs. 2.5 ng/ml (range 0.9–3.4), respectively). Serum levels of cytokines and CRP of survivors and non-survivors are summarized in Table 2. Serum levels of IL-6, TNF and sTNF-R p55 and p75 were higher in non-survivors compared to survivors. However, only values for TNF and sTNF-R p75 were statistically significant (p<0.05). There was no significant difference in IL-6 levels between survivors and non-survivors (median 230 pg/ml (range 8–603) and 601 pg/ml (range 122–1000), respectively), even though the highest IL-6 levels (>1000 pg/ml) were observed in three out of six non-survivors.

**Discussion**

Neutropenic patients with fever are at high risk of mortality due to infectious diseases (19). However, in many febrile episodes no causative organism is found and fever is classified as FUO. It is therefore necessary to identify some additional laboratory parameters other than CRP and cytokines which could identify those patients who are at high risk of mortality. There are only a few studies which report that development of sudden hypcholesterolemia in critically ill patients is associated with mortality (20). We therefore followed the serum cholesterol and cytokine levels in neutropenic patients. In the present study a drastic reduction in serum cholesterol was observed in neutropenic patients with fever. In all six patients who did not survive, a reduction in serum cholesterol persisted during their stay in hospital. In contrast, serum cholesterol levels were higher in survivors and returned to values similar to those prior to the onset of fever at the time of discharge from hospital.

Previous studies have shown that not only bacterial and viral infections (3, 21, 22) but also inflammatory processes such as trauma (4) or autoimmune diseases (23) are associated with low cholesterol levels. Since all the patients in our study developed hypcholesterolemia, it suggests a possible common mechanism for hypcholesterolemia in inflammatory processes. In accordance with previous studies, we found increased cytokine levels at the onset of fever during neutropenia (11, 24, 25). An increase in serum TNF and its soluble receptors at the onset of fever was accompanied by a reduction of cholesterol, possibly due to increased removal of circulating lipoproteins (18) or diminished synthesis rates (26).

In summary, our data, even though based on a small number of patients, indicate that serum cholesterol is a reliable marker for prognosis and may serve as an additional therapy control in neutropenic patients with fever. However, it needs to be confirmed on a larger cohort. The association of hypcholesterolemia with increased cytokine levels supports the hypothesis that the systemic release of cytokines plays a role in lowering cholesterol during inflammation.
